1. Explain behaviour of hub device

layer - 1 Device

Whenever the data is going to hub device, will do Broadcast. Hub is used to connect multiple device. Example A device B device and C device. A device is sending with B, that time Hub will be broadcast (also open the data C will not open the data according professional ethics). Hub device are like motherboard circuit are one way like Bus topology at a time A device send the data from B device at a time C device also send the B device with in traffic and collision some network losses that is a system learn from like wiki.

2. Explain behaviour of switch device

Taki - This called Half Duplex in overcome with Switch

Whenever the data going to switch device will do Address learning in mac table. Like Port no, Source mac are note the Table next Destination mac address in the mac table the switch. If there is an entry, it will be act as unicast. If there is no entry the table it will be act as broadcast. Switch behaviour has broadcast + unicast. It is used to connect multiple device. This is only act same network not different network it is layer 2 device. It contain mac table. Like port no, source mac. That is Address learning.

3. Explain behaviour of router device

Whenever the data is going to Router device, destination IP routing Table. If there is an entry, it will be act as unicast. If there is no an entry it will be ~~not~~ ~~not~~ dropped the data. Router is used connect different network. Router are Department to Department are using the Router device. Router are assign the IP address with first IP in like example Interface e0/e1/e2 Three Interface in different NW of Router. Router contain routing table network ID, Interface name, Prefix length. Router contain routes. Whenever assign the IP address in router, router are directly connected routes. It is a layer 3 device. Router break the broadcast domain. It is a unicast device.
